Report ID: Recording 3

Patient Name: N/A

Age: N/A

Sex: N/A

Exam Type: N/A

Date: N/A

Clinical History

Patient reports left knee pain for more than a year. The pain increases with cold weather and exposure to cold water, and decreases with warmth. The onset was sudden, and the pain is constant. There is no swelling or giving way of the knee. Morning stiffness lasts less than ten minutes if the weather is cold. No other joint issues reported. No history of back pain or disc problems. Family history includes a relative with a lymphatic condition affecting the knees and another relative with rheumatoid arthritis. The patient has hypothyroidism and takes 100 mg of thyroxine daily. Lives on the third floor with an elevator available. Occasionally smokes socially.

Detailed Findings

- **Left knee pain** — Chronic pain for over a year, exacerbated by cold, relieved by warmth.
- **No swelling or giving way of the knee** — Indicates stability of the knee joint.
- **Morning stiffness less than ten minutes** — Suggests mild inflammatory process, possibly related to weather conditions.
- **Family history of lymphatic condition and rheumatoid arthritis** — Potential genetic predisposition to joint issues.
- **Hypothyroidism** — Managed with 100 mg of thyroxine daily.

Impression Summary

The clinical presentation is consistent with chronic left knee pain, likely exacerbated by environmental factors such as cold exposure. The absence of swelling or instability suggests a non-traumatic etiology. Family history of rheumatoid arthritis and lymphatic conditions may indicate a predisposition to joint issues. Hypothyroidism is well-managed

with medication.

Recommendations

- Consider further evaluation for potential inflammatory or degenerative joint disease.
- Monitor thyroid function regularly.
- Advise on lifestyle modifications to manage symptoms, such as avoiding cold exposure.

Urgency Level: moderate
